

Qingyu Jiang

1、

- 1) The health market is highly regulated and need the approval before entry the market.
- 2) The health market is a vary large and still growing market because of the reasons like aging population, the growth of income, the awareness of heath increasing and so on.
- 3) The products need a long time developing and very costly.

2、

- 1) Big pharmaceutical companies have existed for years and very powerful in the market, but they are more risk adverse and more traditional, while the Startups are very younger but often innovative and risk taking.
- 2) Big pharmaceutical companies cover more disease areas, while Startups usually focus on one specific area or platform.
- 3) In Big pharmaceutical companies there are many employees, so they just screws on machine, while in Startups employees plays more important roles and have more freedom.

3、

1) Doctors:

Doctors give feedback on the drugs and help instruction the user of the product, which ensure the product effective and safe.

2) Patients:

Patients are the ones who really use the product, so they can share how the products affect their health, which help pharmacies to adapt the product.

3) Insurance companies:

Insurance companies can affect if the product succeed in the market because they decide if they will cover the cost of the product for patients, which will make the products affordable.

4、

1) Patients with chronic skin diseases: They are the main users of our products, and their feedback and results are crucial to our product design.

2) Skin doctors: They can provide professional advice to help promote and improve our products, ensuring the professionalism and safety of the products.

3) R&D team: Our R&D team is the original designer and tester of the mask. Their efforts ensure the effectiveness of the mask and its unique advantages in the market.

5、

1) BioTech is the use of biological methods to treat diseases, such as using gene editing or cell cloning to treat diseases.

Example: Genetic testing of newborns, or chromosome screening to prevent diseases.

2) MedTech is referring to the use of technology by doctors to help detect patients' diseases or manage their health.

Example: Doctors use X-rays to help diagnose.

3) Digital health may refer to the use of digital technology to manage patients' health.

Example: Using wearable devices to monitor patients' heartbeats and heart rates, and the information collected helps doctors understand the patient's health status.

6、

1) Cooperation with the industry

Academic institutions and the industry will have close cooperation, the two complement each other, and accelerate the research results to the market.

2) Funding support:

In the early stages of entrepreneurship, start-ups often lack funds, and academic institutions often have some foundations to provide entrepreneurs with the first pot of gold.

3) Provide theoretical basic research

Academic institutions not only conduct applied research, but also focus on exploring basic scientific principles, which provides theoretical endorsement for scientific and technological innovation.

7、

Cold conflict is a situation that seems calm on the surface, but actually there are contradictions and disagreements in the heart. In a cold conflict, both parties may be silent, uncooperative, indifferent or evasive. Hot conflict is the opposite. Hot conflict will be more intense. Both parties may express their dissatisfaction through anger or quarrels. Emotional expression may escalate the conflict.

Solution:

For cold conflict, the biggest problem is that both parties do not communicate. Therefore, it is necessary to create opportunities for both parties to

communicate openly, explore their inner thoughts and needs, enhance empathy, and actively solve problems instead of avoiding them.

For hot conflict, intense emotions may make it difficult to find the essence of the problem. The most important thing is to let both parties calm down first. They can adjust by temporarily separating or finding neutral people. After both parties calm down, they can discuss to prevent emotional language from making the conflict more and more serious.

8、

A person's emotional state, such as stress, depression, or happiness, will affect their interpretation of other people's words or actions. When people are in a negative mood, they may be more likely to cause conflict.

A person's past experiences will affect their judgment of specific situations. People with different experiences look at things from different perspectives. A person who is often deceived will find it difficult to trust others.

If two people come from different cultural backgrounds, this culture will affect people's behavior and communication methods. People from different cultural backgrounds may express politeness and respect differently, which may lead to misunderstandings.

9、

The value proposition clearly communicates the company's market position and service targets through a statement. Specifically, it answers the question of why users should buy your product.

Since our team is just formed, we have not yet discussed our company's value proposition, but in my opinion, we provide a simple and effective way to provide patients with chronic skin conditions with customized hydrogel masks that use natural ingredients to help soothe the skin, reduce irritation, and provide deep hydration.

This proposition highlights customization and ease of use, highlights the convenience of the mask, and also introduces the function of the mask.

10、

During my time as a student council department leader in university, I didn't know how to delegate tasks at first, so I ended up doing most things myself and became very tired. Later, I learned to assign tasks to others and trust them. This made my work easier and improved my relationships with my team.

The journey of a biotech startup is full of risks and challenges. Unlike regular startups, biotech companies face strict market regulations, longer development cycles, and even potential ethical concerns, which make their life cycle stand out. However, this complex market environment also brings opportunities. The huge and ever-growing market attracts more and more entrepreneurs, and a successful medical product can change lives and improve the quality of life.

A World-Changing Idea

All stories begin with an innovative idea. Before a company is even founded, the founders often identify an unmet need and come up with a creative solution—like developing new tools for diagnostics or creating treatments for diseases affecting many people. But it's crucial that the idea has a solid scientific foundation and feasibility. At this stage, the biggest challenge isn't the idea itself, but proving its technical feasibility. Entrepreneurs need to think not only about the science behind the idea but also about its business potential.

The initial team often does a lot of scientific and market research, collaborates with academic institutions or labs, and applies for grants from universities and society to help fund early R&D. Protecting intellectual property is also critical at this point—early patent applications often lay the groundwork for future financing and growth.

Bringing the Product to the Real-Life

Once R&D progresses, clinical trials become the next big step. This is the necessary stage to prove whether the product is safe and effective for real patients.

Clinical trials are very expensive and can take a long time (3 to 5 years or more), and they come with high risks. For example, a product might perform well in animal testing but fail in human trials, or it could show serious side

effects. Worse yet, if funding issues arise at this stage, the entire project could come to a standstill since clinical trials and earlier R&D don't bring in any profits for investors.

To tackle these challenges, the clinical design and planning must be reasonable, and it's crucial to engage with regulatory agencies (like the FDA or EMA) early to avoid unnecessary delays. Strengthening ties with partners and investors, building trust, and collaborating with hospitals and clinical trial companies can also improve trial efficiency.

Funding – The Lifeline of Biotech Companies

Funding is a constant issue for biotech startups, from early seed rounds to later-stage like venture capital. Each phase requires a significant amount of money. Even projects with huge technical potential can run into trouble if funding dries up. Investors are usually cautious about biotech projects due to the high risks and uncertainties in the industry. The long development cycles, large funding needs, and especially the expensive clinical trial phases mean that a shortage of funds could halt the entire project.

To solve the funding issues, looking for diverse funding sources, including government research grants, venture capital, or partnerships with big pharmaceutical companies, are key to overcoming financial bottlenecks. Entrepreneurs must always be ready to demonstrate the potential of their technology to investors and provide reliable market analysis.

Finding the Real “Customers”

After passing clinical trials and gaining regulatory approval, entering the market becomes a decisive phase. Unlike traditional tech companies, biotech startups often need to spend more time working with doctors, hospitals, and even insurance companies rather than directly targeting consumers. Take Medtronic, for example—they developed a new type of pacemaker, but their true success came from close cooperation with doctors and hospitals, ensuring the product's widespread adoption.

Even after getting regulatory approval, integrating into the healthcare system is a major challenge. Hospitals and doctors can be slow to adopt new products, and patients may be hesitant about them. To address this, building a strong marketing team focused on communication with healthcare providers is essential. Considering reimbursement policies in advance is also important since many innovative medical products may struggle to expand if not covered by insurance.

Exit or Expand

Not all biotech startups aim for an IPO as their end goal. In fact, many successful biotech companies eventually choose to be acquired by large pharmaceutical or medical device companies. This is often a logical outcome, because larger companies have more market resources and R&D capabilities to help startups bring their technologies to a broader market.

Conclusion

The journey of a biotech startup is full of challenges, with each phase presenting its own unique risks and opportunities. From the initial idea and R&D to finally entering the market and potentially exiting, entrepreneurs need not only a strong scientific background but also sharp business acumen. Through proper strategic planning, solid partnerships, timely funding, and an appropriate exit strategy, biotech startups can navigate this long and uncertain road toward success. Of course, many companies may fail at some point along the way, but each attempt lays the groundwork for future success.
